(54) Title: SUPERELASTIC ENDODONTIC INSTRUMENT, METHOD OF MANUFACTURE, AND APPARATUS THEREFOR

## (57) Abstract

A superelastic endodontic instrument, such as a file (11), is formed by grinding a superelastic wire (8) to form a file preform or blank (12), and rotating a first end of the blank (12) while preventing rotation of a second end of the blank (12). The file blank (12) is maintained in the austenite phase at least until twisted to form a stress induced martensite which is plastically deformed by the twisting. A heat treatment step may be performed prior to twisting, during twisting or after twisting of the preform or blank (12). The file blank (12) may be heated by electrical heating methods or by submerging the blank in a heated liquid (234).

## **SUPERELASTIC ENDODONTIC INSTRUMENT, METHOD OF MANUFACTURE, AND APPARATUS THEREFOR**

### **Related Applications**

This application is a continuation-in-part of U.S. Patent  
5 Application Serial No. 08/938,507 filed on September 26, 1997, the  
disclosure of which is hereby fully incorporated by reference herein.

### **Field of the Invention**

The present invention generally relates to superelastic  
endodontic instruments and, more specifically, to instruments such as files  
10 or reamers and methods and apparatus for manufacturing such instruments.

### **Background of the Invention**

Over the past several years, endodontic instruments such as  
root canal files have been manufactured by simultaneously grinding and  
twisting thin carbon steel or stainless steel rods or wires. Specifically, steel  
15 wire blanks are first ground to the desired cross sectional shape, such as  
square, triangular or rhomboid, and to the appropriate size and taper. The  
ground blank is then gripped at one end and spring loaded jaws are brought  
into contact with the ground portion of the blank. As the blank is rotated  
from the gripped end, the jaws are moved axially away from that end. The

jaws therefore twist the rotating blank and form helical flutes into the blank. The longitudinal, ground edges of the blank form helical cutting edges on the file. The axial jaw speed, twisting speed and spring force are controlled to obtain the desired helical configuration.

5                   With the emergence of superelastic materials, such as nickel titanium alloys, endodontic instrument manufacturers are now able to form endodontic root canal files with much more flexibility. This greatly assists the endodontist during use of the file in a root canal procedure. The use of superelastic material, however, causes some significant manufacturing  
10 concerns due to the tendency of the material to return to its original shape after the release of an applied force. File blanks manufactured of superelastic materials generally react in this manner to the conventional twisting methods employed for manufacturing carbon and stainless steel files. Moreover, if superelastic file blanks are over-stressed, such as by  
15 being twisted too much during the fluting procedure, the material is subject to failure. For reasons such as these, current manufacturers of endodontic files may resort to grinding the helical profile directly into the superelastic blanks while applying no twisting forces to the blanks. These direct grinding methods are time consuming and expensive. They also limit the  
20 variety of cross sectional shapes that may be formed in the final product.

With the above background in mind, it would be desirable to provide a method of manufacturing a wide variety of superelastic endodontic appliances, such as files, using twisting and grinding techniques. In short, it would be advantageous to retain the benefits of

superelastic materials and the benefits of a twisting and grinding procedure that simplifies manufacture and allows the production of a wide variety of file cross sections.

### **Summary of the Invention**

5                   The present invention provides a superelastic endodontic instrument, which is preferably a file or reamer, having increased torsional and bending flexibility, as compared to conventional steel files, and manufactured by improved processes relative to prior superelastic file production techniques. Generally, the invention provides a process in which  
10   a superelastic endodontic instrument preform or blank may be ground and then twisted with plastic deformation, that is, maintenance of the twisted shape, without over-stressing the material into failure.

                  The unique process of this invention involves maintaining the instrument blank in the austenite phase of the superelastic material at least  
15   prior to twisting and, preferably, prior to and during the twisting operation. To maintain the blank in the austenite phase, the blank is preferably maintained above the austenite finish temperature ( $A_f$ ) of the particular superelastic material. The blank is more preferably maintained in the working temperature range  $T_w$  of the superelastic material. For a wide  
20   variety of superelastic alloys, this range would be between 200°F - 400°F. The material of the blank is converted from the austenite phase to the martensite phase by the stress applied during the twisting operation. The material undergoing stress induced martensite transformation is plastically

deformed during twisting so that the fluted profile is retained after completion of the twisting process. Due to the ability to pregrind a file blank, for example, it is possible to fabricate a superelastic endodontic file having many different transverse cross sectional shapes, such as those  
5 conventionally obtained with steel materials.

In another aspect of this invention, the elevation in temperature to the austenite finish temperature  $A_f$  of the superelastic blank may be accomplished through several different methods, such as ambient, induction, joulian, or radiant heating, or submersion within a heated liquid.  
10 Ambient heating, for example, may be accomplished in an oven while induction heating may utilize an inductive heating coil surrounding the blank during the twisting operation.

Submersion within a heated liquid can allow the blank to be heated in a rapid and controlled manner. The heated liquid may be oil or a  
15 salt solution, or other liquids that do not boil below or close to the  $A_f$  of the particular superelastic metal. Fluting apparatus is provided generally above a vessel containing the liquid and includes a rotary motion mechanism for holding and rotating an instrument blank, such as a file blank, a clamping mechanism that receives a ground portion of the file blank and a linear or  
20 axial motion mechanism for moving the clamping mechanism along the longitudinal axis of the file blank at a rate which is proportional to the rate of rotation. According to this heating alternative, the twisting operation is preferably performed with the ground portion of the blank submerged in the heated liquid. After the twisting process is complete, the fluted,

superelastic file may then undergo subsequent quenching or heat treatment operations in order to achieve the desired physical properties.

Additional objects and advantages of the invention will become more readily apparent to those of ordinary skill in the art upon review of the following detailed description of the preferred embodiment taken in  
5 conjunction with the drawings.

### **Brief Description of the Drawings**

Fig. 1 is a schematic perspective view of one type of apparatus used in fabricating a superelastic file in accordance with the  
10 present invention.

Fig. 1A is a side view of a file formed on the apparatus of Fig. 1.

Fig 1B is an enlarged cross-sectional view taken on line 1B-1B of Fig. 1A.

15 Fig. 2 is a schematic side view of one apparatus for forming a flat surface along the length of a file blank.

Figs. 2A, 2B, 2C and 2D are transverse cross-sectional views, perpendicular to the longitudinal axis of the finished file or the file blank using the apparatus of Fig. 2 or Fig. 6.

20 Fig. 3 is a schematic side view of an apparatus similar to Fig. 2 for forming a concave surface along the length of a file blank.

Figs. 3A, 3B and 3C are transverse cross-sectional views, perpendicular to the longitudinal axis of the finished file or the file blank,

showing concave surfaces formed on file blanks, using the apparatus of Fig. 3.

Fig. 5 is a perspective view of another apparatus for forming  
5 flat surfaces along the length of a number of file blanks.

Fig. 6 is a perspective view of the apparatus used in  
straightening superelastic wire.

Fig. 7 is a schematic elevational view of another type of  
apparatus used in fabricating a superelastic file of the present invention in  
10 conjunction with a heated liquid.

Fig. 8 is a bottom view of the apparatus shown in Fig. 7.

#### **Detailed Description of the Preferred Embodiments**

Superelastic materials are typically metal alloys which return to  
15 their original shape after substantial deformation. Superelastic alloys such  
as nickel titanium (NiTi) can withstand several times more strain than  
conventional materials, such as stainless steel, without becoming plastically  
deformed. Further, a superelastic material will generally recover  
approximately 6% after twisting at ambient temperature while a stainless  
20 steel will recover only 1-2% after twisting. Typically, superelastic alloys  
undergo a stress induced martensitic transformation which allows for shape  
memory properties. Shape memory and superelasticity are found in  
stoichiometric NiTi, near-equiatomic Ni-Ti, for example, 50.8 atomic percent  
Ti and 49.2 atomic percent Ni, Ni-Ti-Cu, Ni-Ti-Nb and Ni-Ti-Fe alloys as well

as beta-phase titanium or other Ti based alloys. Examples of suitable nickel-titanium alloys in various stoichiometric ratios are disclosed in U.S. Patent No. 5,044,947 (nickel-titanium-copper alloy) and U.S. Patent Applications 08/221,638 and 08/454,016, inventor Sachdeva et al.,  
5 entitled "NiTiNb Alloy Processing Method and Articles Formed Thereby" (nickel-titanium-niobium-alloy). The disclosures of U.S. Patent 5,044,947 and the aforesaid applications are hereby incorporated by reference.

The specific alloy composition used for the endodontic instrument of this invention is not critical as the invention may utilize many  
10 materials which exhibit superelastic characteristics. U.S. Patent No. 5,429,501, which is hereby incorporated in its entirety by reference herein, discloses superelastic and shape memory beta-phase titanium. To form beta-phase titanium, metallic titanium may be alloyed with molybdenum, chromium, zirconium, tin, vanadium, iron or niobium. Other compositions  
15 such as Cu-Zn alloys are also known to be superelastic and are suitable for use in the present invention. Another material suitable for use in the present invention is a work hardened nickel titanium having a martensitic crystal structure, such as that sold under the tradename NITANOL for orthodontic wires by Unitek Corp., Arcadia California.

20 Superelastic materials have a temperature range in which the material may be permanently deformed. This range is known as the working temperature range  $T_w$ . When a superelastic wire is heated to a temperature in the working temperature range  $T_w$ , the wire may be permanently deformed so that when the wire is cooled, the deformed shape

is maintained. Typically, the superelastic wire is packaged in coils and should be straightened prior to grinding and twisting. One method of straightening the wire 8 is to wrap the wire around a mandrel 160 as shown in Fig. 6. The mandrel 160 is then placed in a furnace and the wire 8 is heated into the  $T_w$ . The wire 8 is then cooled, removed from the mandrel and the curved ends are trimmed.

Superelastic alloys are in the martensitic phase when they are below the austenitic transformation temperature  $A_f$ , i.e., the temperature at which the material is about 100% austenite. These alloys retain their deformed shape when subjected to stress in the martensitic phase. However, the shape memory property returns the deformed material to its original predeformation configuration when heated above  $A_f$ . In the present invention it is preferred to use an alloy having an  $A_f$  temperature lower than about 37° C (i.e., body temperature) so that the instrument will be in the austenitic phase during use in the human body.

When the superelastic material is twisted, the material may form a stress induced martensite phase since less energy is necessary to stress induce and deform martensite than to deform austenite. If the file preform is deformed at room temperature and there is not enough strain to induce plastic deformation of the martensite phase, the wire will spring back to its original shape once the twisting force is released. It is also possible to permanently deform superelastic material by heating within the  $T_w$  range prior to and during twisting. A typical superelastic material will have a  $T_w$  range of 200°F - 400°F. Another method of permanently

deforming a preform or blank according to the invention is by performing a rapid twist step to heat the superelastic material by internal friction to a temperature at which the material forms a stress induced martensite.

As used herein, the terms shape-memory alloy and superelastic material or alloy or similar terms are intended to include all suitable alloy compositions which possess shape-memory and/or superelastic properties, respectively. Moreover, the term superelastic is intended to mean the ability of a material to withstand at least twice as much strain as stainless steel materials can withstand without plastic deformation. The term shape memory is intended to mean the ability of a wire to recover to its original state by the use of temperature. The term rhombus or rhomboidal is intended to define a geometric shape, having four major sides, which is, substantially a parallelogram, i.e., including four equal sides and no internal right angles.

The files and file-forming processes of this invention are implemented, in one preferred embodiment, with an apparatus such as apparatus 10 depicted in Fig. 1. Prior to twisting, file preforms or blanks are ground to the desired shape, including length, transverse cross-section and taper, on any one of the devices shown in Figs. 2, 3, or 5.

Referring to Fig. 2, cylindrical superelastic rods or wires 8 are ground to form file preforms or blanks 12 which are subsequently twisted to form helically fluted files 11. Cylindrical rod or wire 8 is mounted into collet 52 which is fixedly mounted upon a stage 54 which is selectively horizontally movable in opposite directions as designated by arrows 55a and

55b. Once rod 8 is mounted in the collet 52, grinding wheel 50 is lowered into contact with the rod 8. Stage 54 is then advanced horizontally rightwardly, as is seen in Fig. 2, to move collet 52 and rod 8 axially so that a flat surface 101 is ground on one side of the rod 8. After one such flat, that is, flat surface, has been ground along the working length L (see Fig. 1A) of the rod, grinding wheel 50 is lifted vertically, and stage 54 is moved axially leftwardly to the initial or home position so that the grinding wheel 50 is aligned with the upper portion of the inner end of the working length of the partially ground rod. Collet 52 is then indexed about its central axis by a predetermined angle, the magnitude of which depends on the number of flutes desired in the finished file. Indexing rotational angles of 180°, 120° and 90° are employed for 2, 3 and 4 flute files, respectively. It is also possible to rotate the collet by a series of angles (e.g. 60°, 120°, 60°) to obtain a file preform having a rhomboidal cross section. Grinding wheel 50 is then lowered to the desired depth of contact with the rod 8, and stage 54 is then moved rightwardly to move rod 8 axially past grinding wheel 50 to grind the second flat surface on the file blank. The foregoing process is repeated until all the flats have been ground on the file blank.

As noted, by varying the angle which collet 52 indexes rod 8, it is possible to form file blanks having three or more apices 103 shown generally in Figs. 2A-2C. The apices 103 of the preground file blank, once twisted, and permanently helically fluted, form the cutting edges of the helically fluted file. Typically, endodontic files include three or four apices or helical cutting edges 103.

In order to form a file blank having a square transverse cross section as shown in Fig. 2A, rod 8 is indexed  $90^\circ$  after each flat surface 101 is ground. In order to form a file blank having three apices and a triangular transverse cross section, the rod is indexed  $120^\circ$  after each flat surface is formed (as shown in Fig. 2B). Using the method of the present invention it is also possible to form a file having a rhomboidal transverse cross section (Fig. 2C). This is accomplished by grinding a first flat surface 101c<sub>1</sub>; indexing the rod  $60^\circ$  clockwise as viewed in Fig. 2C and grinding a second flat surface 101c<sub>2</sub>; indexing the rod  $120^\circ$  clockwise as viewed in Fig. 2C and grinding a third flat surface 101c<sub>3</sub>; and indexing the rod  $60^\circ$  clockwise as viewed in Fig. 2C and grinding the fourth flat surface 101c<sub>4</sub>. It is not necessary to change the initial depth of cut of the wheel to fabricate the square, triangular and rhomboidal preforms shown in Figs. 2A-2C, respectively. However, in order to fabricate a preform having a rectangular cross-section, as shown in Fig. 2D, the initial depth of cut may be adjusted prior to forming each flat side or may be adjusted after opposing pairs of edges are ground. For example, as seen in Fig. 2D, a first flat side 101d<sub>1</sub>, is ground; the rod 8 is then indexed  $90^\circ$ , the initial depth of cut reduced and a second flat side 101d<sub>2</sub> is ground; rod 8 is then indexed  $90^\circ$ , the initial depth of cut is increased to the depth used for the cut of side 101d<sub>1</sub> and a third flat side 101d<sub>3</sub> is ground; rod 8 is then indexed  $90^\circ$ , the initial depth of cut is reduced to the depth used for the cut of side 101d<sub>2</sub> and fourth side 101d<sub>4</sub> is ground. It is also possible to grind flat side 101d<sub>1</sub>, index the rod  $180^\circ$ , and grind flat side 101d<sub>4</sub>; index the rod  $90^\circ$  and

decrease the initial depth of cut and grind flat side 101d<sub>2</sub>; and finally index the rod 180° and grinding the final flat side 101d<sub>3</sub>.

It is possible to form a variety of different cross sectional shapes by varying the surface of the grinding wheel and/or the index  
5 angles. For example, by dressing the surface of grinding wheel 50 so that the surface is convexed, as shown in Fig. 3, it is possible to form ground surfaces 105 having the concave shapes shown in Figs. 3A, 3B and 3C, rather than the flat shapes of the surfaces 101 shown in Figs. 2A, 2B and 2C. When the surface of the grinding wheel 50 is convexed, the angle A of  
10 the apices 107 (Fig. 3A) is more acute for a file having the same index angle and number of sides than is angle A' of the apices 103 (Fig. 2A) when the surface of the grinding wheel 50 is flat (Fig. 2). While angle A is more acute and provides a sharper cutting edge, that edge is weaker due to the lower amount of material at the apex. Thus, the apices shown in Figs.  
15 2A-2C are more rugged to maintain a usable edge and provide for a longer working life.

Another device for grinding cylindrical rods 8 is shown in Fig. 5. Fig. 5 shows a wide grinding wheel 120 which moves transversely to the longitudinal axes of a large number of rods 8 to grind a flat surface onto  
20 the rods. The cylindrical rods 8 are placed upon rest 122. The rods 8 are disposed in parallel and extend along substantially the entire width of the rest 122. The parallel rods 8 are held by retainer 124 which is movable along the length of rest 122 as shown by opposing arrows 128a and 128b. Movable retainer 124 includes lateral projection 124a which extends over

an end portion of rods 8 to secure the rods to rest 122 and prevent the rotation of the rods during grinding. Once rods 8 are retained between the lateral projection 124a and the rest 122, grinding wheel 120 moves back and forth across the width of rest 122 to grind a flat surface on the entire  
5 working length of each rod 8. Typically, the grinding 120 wheel moves across each rod twice, once while traveling away from projection 124a and once while traveling toward projection 124a. During grinding, the wheel 120 may be moved straight across the rods or may move in a figure eight or zigzag pattern. The grinding wheel is preferably a porous wheel such as  
10 an ANSI standard C-60IV wheel rotating at rate between 3,000 and 8,000 surface feet per minute and preferably about 5,000 surface feet per minute. The material is passed under the wheel at a feed rate between about 50 and 100 lineal feet per minute, and preferably about 75 lineal feet per minute.

15 After grinding a first flat side, the movable retainers 124 is translated with respect to the rest 122. The lateral projection 124a of the retainers 124 remains in contact with rods 8 so that the movement of the retainer along the direction shown by arrows 128a, 128b causes each rod to rotate by a predetermined angle about the longitudinal axis of the rods 8.  
20 Once the rotation is complete, a second flat surface is ground across the working length of the rod. Depending upon the desired cross section of the file 11, the rods 8 are typically rotated and ground one or more times.

After the superelastic file blanks have been ground to the desired cross-sectional file preform shape they are preferably heated to a

temperature above ambient temperature prior to, during and subsequent to the twisting operation using thermal or frictional energy or a combination thereof. This temperature is preferably above the austenite finish temperature  $A_f$  of the particular superelastic material and can be as high as  
5 the working temperature range  $T_w$  of the material.

The heating process may externally heat the wire preform in the collet 14 by the provision of induction coils, radiant heating elements or electrodes to provide for joulian heating. The temperature to which the preform is heated is based upon the specific alloy used. A temperature  
10 range of 200°F - 400°F is contemplated to be typical. Alternatively, the files can be heated without the application of heat from an external heat source by twisting rapidly so that internal friction heats the file.

Once the file preforms are formed, they are twisted or heated and twisted on a device such as that shown in Fig. 1. The twisting  
15 apparatus 10, shown in Fig. 1, includes a drive head 9 which rotates about a horizontal axis. Extending from the drive head 9 is a collet 14 which circumferentially grips and secures the proximal or inner end of a preformed ground file blank 12 for rotation about the longitudinal axis thereof. The distal or outer end portion of the file blank 12 is secured by opposing jaws  
20 20, 22, which are mounted on a stage 28 which moves parallel to the longitudinal axis of the file blank (horizontally as shown in Fig. 1), away from collet 14 at a predetermined rate as the collet rotates to twist the file blank 12. At least one of the jaws includes a spring or air cylinder 16 so that it may be compressed against the opposing jaw with a constant force.

Each jaw includes a protectant layer 24, 26 which is malleable and able to withstand the working temperature of the file blank 12. Brass is one material known to be suitable. With each subsequent file formed, the jaws 20, 22 are provided with a new protectant layer 24, 26 from strips 29, 30 from a source 32, 34 such as take-off reels. The protectant layer may optionally be contacted by a heating element 25, 27 which may heat by any suitable process, such as an electrical heating process of joulian, radiant or induction heating or may be supplied with a heated fluid such as steam or oil.

10 In order to optimize the superelastic properties of the finished file it is desirable, although not essential, to heat treat the twisted files. The heat treatment may be performed in any furnace with air circulation. The radiant heating elements or electrodes to provide for joulian heating can be used for the post twist heat treatment.

15 Typically the files are made in a variety of working lengths varying from 19-30 mm. The specific variables which are typically controlled in fabricating such files are set forth in the Tables 1 and 2. In Tables 1 and 2 the variables A and B represent the minimum thickness of the transverse cross section at 16.00 mm and 3.00 mm, respectively, from the tip. The variables C and D represent the maximum thickness of the transverse cross section at 16.00 mm and 3.00 mm, respectively, from the tip.

Table 1 describes the characteristics of a twisted rhomboidal file. In observing the longitudinal cross section of a rhomboidal file there

are alternating large flutes 153, resulting from the major axis of the rhombus, and small flutes 151, resulting from the minor axis of the rhombus. In Table 1 the column entitled Tight Flute Limit includes two values. The first value is the minimum acceptable length of a small flute 151 resulting from the twisting of the minor axis of the rhombus. The second value is the minimum acceptable length of a large flute 153 resulting from the twisting of the major axis of the rhombus. Similarly, the column entitled Loose Flute Limit includes two values. The first value is the maximum acceptable length of a small flute 151 resulting from the twisting of the minor axis of the rhombus. The second value is the maximum acceptable length of a large flute 153 resulting from the twisting of the major axis of the rhombus. In Table 1 the column labeled T max represents the maximum acceptable length of the untwisted portion at the distal tip of the file. In Table 2 the value L is the length of the ground portion of the rod.

Referring now to Fig. 7, an apparatus 200 is shown for forming a superelastic endodontic file blank 202 into a fluted, superelastic file. File blank 202 has been ground, such as in accordance with the above descriptions, before being fluted by apparatus 200. Apparatus 200 generally comprises a rotary motion mechanism 204 operatively connected to a linear or axial motion mechanism 206 similar to apparatus 10 of Fig. 1. Each mechanism 204, 206 is connected to file blank 202 for purposes to be described. Rotary motion mechanism 204 and linear motion mechanism 206 may be conventional mechanisms known in the art for forming helical

flutes on endodontic files. Each mechanism 204, 206 is operated by a suitable electric motor 210. A gear drive 212 is connected in a conventional manner between an output 210a of motor 210 and linear motion mechanism 206 to convert the rotary motion of motor 210 into linear motion. Gear drive 212 is shown to simply include two gears 212a, 212b, for simplicity, but it will be understood that idler gears may be used between gears 212a, 212b. Such idler gears are conventionally used to set the material feed rate. A support plate 220 is provided generally for connecting rotary motion mechanism 204 to linear motion mechanism 206.

Support plate 220 can also serve as a mounting plate for a mechanism (not shown) used to raise and lower apparatus 200, for reasons to be described.

Rotary motion mechanism 204 further comprises a rotary shaft 222 which may be directly coupled to output shaft 210a of motor 210. A conventional collet 224 is provided for holding a proximal end of superelastic file blank 202. Superelastic file blank 202 further has its ground portion or working length held between a pair of spring-loaded clamping jaws 226, 228, as best shown in Fig. 8. Clamping jaws 226, 228 are held at a relative lower end 230a of a clamping jaw support 230. Clamping jaw support 230 preferably has a conventional biasing mechanism to force jaws 226, 228 toward one another with a desired clamping force. Further, clamping jaw support 230 holds a helical threaded shaft 232 for rotation at a relative upper end 230b. Helical threaded shaft 232 is also held within internal threads of gear member 212a of gear drive 212 such that, upon operation of gear drive 212 by motor 210, gear member 212a

will rotate and also rotate helical threaded shaft 232. This will move shaft 232 linearly along its longitudinal axis thereby moving jaw support 230 and jaws 226, 228 along the length of the pre-ground superelastic file blank 202.

5                   In accordance with one aspect of the invention, a heated liquid 234 contained in a vessel 236 receives the ground portion of file blank 202 during a twisting and fluting operation. The heated liquid media 234 may, for example, comprise a salt solution or other suitable liquids such as oil. Preferably, the chosen liquid will have a boiling temperature preferably  
10   above the  $A_f$  temperature or even above the  $T_w$  of the particular superelastic material. Presently, it is contemplated that a suitable operating temperature for liquid 234 is approximately 500°C or above. Again, it is preferable that the liquid does boil at the chosen operating temperature. Liquid 234 may be heated by any conventional manner, such as with an  
15   electrical heating element 238 or a heating jacket.

For purposes of describing the operation of the apparatus 200 shown in Figs. 7 and 8, one contemplated example involves placing a ground file blank 202, formed of a superelastic metallic alloy and formed with a rhomboid cross section as generally described above, within collet  
20   224. Clamping jaws 226, 228 may then be placed about a proximal, ground end of file blank 202 adjacent collet 224. Apparatus 200 may then be lowered toward a heated liquid comprised of a salt solution heated to a temperature of about 500°C. Blank 202 should be lowered until the ground portion is submerged within heated liquid 234. After about five seconds, a

fluting operation may be carried out by moving linear or axial motion mechanism 206 downwardly at a speed of about 6 inches/min. Rotation of blank 202 may be carried out by mechanism 204 at a corresponding rate which forms a desired number of twists. When the fluting jaws 226, 228 reach the relative lower tip end of ground file blank 202, the fluting operation is complete and apparatus 200 may be lifted from heated liquid 234 and removed from collet 224. Quenching or heat treating of the finished file may then be carried out if appropriate.

It will be appreciated that different alloy compositions will possess a different shape-memory characteristic, a different transformation temperature ( $A_f$ ), a different modulus of elasticity, and a different working temperature range  $T_w$ . It is within the skill of one in the art based upon the teachings of the present invention to adjust the heating, twisting and heat treating steps based upon the specific properties of the material used.

While the present invention has been illustrated by a description of various embodiments and while these embodiments have been described in considerable detail, it is not the intention of the Applicants to restrict or in any way limit the scope of the appended claims to such detail. Additional advantages and modifications will readily appear to those skilled in the art. The invention in its broader aspects is therefore not limited to the specific details, representative apparatus and method as shown and described. This has been a description of the present invention, along with the preferred methods of practicing the present invention as

currently known. However, the invention itself should only be defined by the appended claims, wherein we claim:

1.           A superelastic endodontic instrument formed by substantial plastic deformation of a blank having a longitudinal axis and formed from a superelastic material, wherein the instrument is formed by the steps of:  
transforming the superelastic material of the blank into an  
5   austenite phase; and  
twisting the blank about the longitudinal axis to form an instrument having helically shaped edges.
2.           The superelastic endodontic instrument of claim 1 wherein the superelastic metal of the blank transforms to martensitic phase during the  
10   twisting step.
3.           The superelastic endodontic instrument of claim 1 wherein the superelastic material is a Ti alloy.
4.           The superelastic endodontic instrument of claim 3 wherein said superelastic material is selected from the group consisting of stoichiometric  
15   NiTi, near-equiatomic Ni-Ti, Ni-Ti-Nb alloys, Ni-Ti-Fe alloys, Ni-Ti-Cu alloys, beta-phase titanium alloys and combinations thereof.
5.           The superelastic endodontic instrument of claim 3 wherein said superelastic material is at least about 40 atomic percent Ti.

6. The superelastic endodontic instrument of claim 1 wherein said instrument is selected from the group consisting of files and reamers.
7. The superelastic endodontic instrument of claim 1 wherein the transforming step includes external heating of the blank.
- 5 8. The superelastic endodontic instrument of claim 1 further comprising heating the blank by internal friction during twisting to maintain the blank in the austenite phase.
9. The superelastic endodontic instrument of claim 1 wherein the blank is transformed to the austenite phase by heating the blank in a bath of  
10 heated liquid.
10. The superelastic endodontic instrument of claim 9 wherein the blank remains submerged in the bath during twisting.
11. A superelastic endodontic instrument formed by substantial plastic deformation of a blank having a longitudinal axis and formed from a  
15 superelastic material, wherein the instrument is formed by the steps of:  
heating the blank to transform the superelastic material to an austenite phase; and  
twisting the blank about the longitudinal axis to form an instrument having helically shaped edges.

12. The superelastic endodontic instrument of claim 11 wherein the superelastic material transforms to martensitic phase following the twisting step.
13. The superelastic endodontic instrument of claim 11 wherein  
5 the superelastic material is a Ti alloy.
14. The superelastic endodontic instrument of claim 13 wherein said superelastic material is selected from the group consisting of stoichiometric NiTi, near-equiatomic Ni-Ti, Ni-Ti-Nb alloys, Ni-Ti-Fe alloys, Ni-Ti-Cu alloys, beta-phase titanium alloys and combinations thereof.
- 10 15. The superelastic endodontic instrument of claim 13 wherein said superelastic material is at least about 40 atomic percent Ti.
16. The superelastic endodontic instrument of claim 11 wherein said instrument is selected from the group consisting of files and reamers.
17. The superelastic endodontic instrument of claim 11 wherein  
15 the heating step includes external heating of the blank.
18. The superelastic endodontic instrument of claim 11 wherein the heating step includes heating of the blank by internal friction during twisting.

19. The superelastic endodontic instrument of claim 11 wherein the heating step is performed in a bath of heated liquid.
20. The superelastic endodontic instrument of claim 19 wherein the bath is comprised of a salt solution.
- 5 21. The superelastic endodontic instrument of claim 19 wherein the bath is comprised of oil.
22. A method of forming a superelastic endodontic file from a performed wire blank comprising a superelastic material and having a longitudinal axis and a predetermined transverse cross-sectional shape with  
10 apices for defining longitudinal edges along a working length of the file, the method comprising the steps of:
- twisting the blank about its longitudinal axis to permanently, helically deform said blank and convert said longitudinal edges into helically shaped cutting edges; and
- 15 maintaining the blank in an austenite phase at least until immediately prior to the twisting step.
23. The method of claim 22 wherein the superelastic material transforms to martensite phase during the twisting step.

24. The method of claim 23 wherein the martensite phase is a stress induced martensite phase.
25. The method of claim 24 wherein the stress induced martensite phase includes plastic deformation of the blank during the twisting step.
- 5 26. The method of claim 22 wherein, prior to the twisting step, the method further comprises the step of grinding at least one elongated narrow surface along the exterior of the blank for a distance approximately equal to the working length of the file.
27. The method of claim 26 wherein the predetermined cross-
- 10 section of the blank along the working length has a cross section selected from the group consisting of three-sided and four-sided polygons.
28. The method of claim 27 wherein the predetermined cross-sectional shape is substantially rhomboidal.
29. The method of claim 26 further comprising the step of heating
- 15 the file blank to a temperature above the austenite finish temperature  $A_f$  of the superelastic material prior to twisting.
30. The method of claim 26 further comprising the step of heating the blank to a temperature of about 200°-400° F prior to twisting.

31. The method of claim 29 wherein the heating step is performed by an electrical heating process selected from the group consisting of radiant, joulian and induction heating.

32. The method of claim 29 wherein the heating step is performed  
5 in a bath of heated liquid.

33. The superelastic endodontic instrument of claim 32 wherein the bath is comprised of salt solution.

34. The method of claim 26 further comprising the step of heat treating the blank by heating to a temperature within the  $T_w$  range of the  
10 superelastic material subsequent to the twisting step.

35. The method of claim 34 wherein the maintaining step further comprises heating the blank by an electrical heating process selected from the group consisting of radiant, joulian and induction heating.

36. The method of claim 34 wherein the maintaining step further  
15 comprises heating the blank in a bath of heated liquid.

37. The method of claim 36 wherein the bath is comprised of a salt solution.

38. The method of claim 22 wherein the maintaining step further comprises the step of heating the blank to a temperature above the austenite finish temperature  $A_f$  of the superelastic material during twisting.

39. The method of claim 38 wherein the heating step includes  
5 electrically heating the blank in a process selected from the group consisting of radiant, joulian and induction heating.

40. The method of claim 38 wherein the heating step includes submerging the blank in a bath of heated liquid.

41. The method of claim 40 wherein the bath is comprised of a  
10 salt solution.

42. The method of claim 40 wherein the bath is comprised of oil.

43. The method of claim 38 wherein the heating step is caused by internal friction of twisting, without the application of heat from an external heat source.

15 44. The method of claim 26 wherein the grinding step is performed using a rotary grinding wheel having a surface speed of between about 3,000 and 8,000 surface feet per minute.

45. The method of claim 44 wherein the axis of rotation of the surface of the grinding wheel is concave.

46. The method of claim 44 wherein the axis of rotation of the surface of the grinding wheel is convex.

5 47. The method of claim 26 wherein the grinding step includes the steps of:

supporting at least one of said blanks;

fixing the blank at a predetermined position in relation to the grinding wheel;

10 grinding a first elongated narrow surface along the working length of the blank; and

indexing the blank about its longitudinal axis and subsequently grinding another elongated narrow surface along the working length of the blank.

15 48. The method of claim 47 wherein the blank indexing and subsequent grinding steps are repeated at least twice after formation of the first elongated surface to form a preformed file blank having a substantially triangular cross section.

49. The method of claim 47 wherein the blank indexing and subsequent grinding steps are repeated at least three times after formation of the first elongated surface to form a preformed file blank having a substantially quadrilateral cross section.
- 5 50. The method of claim 47 wherein the blank is indexed approximately 90° during each indexing step.
51. The method of claim 47 wherein the blank indexing steps alternatively index the blank 60° and 120° to form a preformed file blank having a substantially rhomboidal cross section.
- 10 52. The method of claim 47 wherein the grinding step is performed using a rotary grinding wheel having a surface speed of between about 3,000 and 8,000 surface feet per minute.
53. The method of claim 52 wherein the grinding step is performed using a rotary grinding wheel having a surface speed of about 5,000
- 15 surface feet per minute.
54. The method of claim 47 wherein the grinding step is performed using a rotary grinding wheel having a surface speed of between about 3,000 and 8,000 surface feet per minute and a material feed rate of between about 50 and 100 lineal feet per minute.

55. The method of claim 47 wherein the grinding step is performed using a rotary grinding wheel having a surface speed of about 5,000 surface feet per minute and a material feed rate of between about 50 and 100 lineal feet per minute.

5 56. The method of claim 55 wherein the material feed rate is about 75 lineal feet per minute.

57. A method of making a file from a rod formed of a superelastic material and having a first and a second end and a working length therebetween, the method comprising the steps of:

10 grinding the rod to form a file preform having a predetermined length, cross-sectional shape and taper along the working length thereof, the cross-sectional shape having corners which define longitudinal edges along the working length; and  
twisting the preform to permanently helically deform said  
15 preform and form helical shaped cutting edges from said longitudinal edges.

58. The method of claim 57 wherein the preform is maintained in an austenite phase until immediately prior to twisting.

59. The method of claim 57 wherein the preform is transformed to the martensite phase during twisting.

60. The method of claim 57 further comprising the step of heating the preform to a temperature above the austenite finish temperature  $A_f$  of the material prior to twisting.

61. The method of claim 57 wherein the grinding step includes the  
5 steps of:

retaining at least one rod in a predetermined position with respect to a grinding wheel;

grinding a first elongate narrow surface along the working length of the rod; and

10 alternatively indexing the rod about a longitudinal axis thereof and subsequently grinding another elongate narrow surface along the working length of the rod.

62. The method of claim 61 wherein the preform is maintained in the austenite phase of said material until immediately prior to twisting.

15 63. The method of claim 61 wherein the preform is transformed to the martensite phase of said material by twisting.

64. The method of claim 61 further comprising the step of heating the preform to a temperature above the austenite finish temperature  $A_f$  of the material prior to twisting.

65. The method of claim 61 wherein the grinding step is performed using a rotary grinding wheel having a surface speed of between about 3,000 and 8,000 surface feet per minute.

66. The method of claim 64 wherein the grinding step is performed  
5 using a rotary grinding wheel having a surface speed of about 5,000 surface feet per minute.

67. The method of claim 61 wherein the grinding step is performed using a rotary grinding wheel having a surface speed of between about 3,000 and 8,000 surface feet per minute and a material feed rate of  
10 between about 50 and 100 lineal feet per minute.

68. The method of claim 61 wherein the grinding step is performed using a rotary grinding wheel having a surface speed of about 5,000 surface feet per minute and a material feed rate of between about 50 and 100 lineal feet per minute.

15 69. The method of claim 67 wherein the material feed rate is about 75 lineal feet per minute.

70. The method of claim 61 wherein the grinding step is performed with a rotatable grinding wheel having a surface which is convex.

71. The method of claim 61 wherein the grinding step is performed with a grinding wheel having surface which is concave.

72. The method of claim 61 wherein the rod is indexed and ground two times after formation of the first elongate narrow surface to form a  
5 preform having a substantially triangular cross section along the working length.

73. The method of claim 61 wherein the rod is indexed and ground three times after formation of the first elongate narrow surface to form a preform having a substantially quadrilateral cross section along the working  
10 length.

74. The method of claim 61 wherein the rod is indexed approximately 90° after formation of each elongate narrow surface .

75. The method of claim 72 wherein the rod is alternatively indexed approximately 60° and approximately 120° to form a file having a  
15 substantially rhomboidal cross section.

76. The method of claim 57 wherein the grinding step is performed upon a single rod retained in a rotatable collar.

77. The method of claim 57 wherein the grinding step is performed upon a plurality of rods disposed in side-by-side parallel relationship.

78. The method of claim 57 wherein a plurality of rods are retained, in side-by-side parallel relationship, upon a rest by a movable  
5 retainer.

79. The method of claim 57 further comprising the step of: heating the preform by an electrical heating process selected from the group consisting of radiant, joulian and induction heating.

80. The method of claim 57 further comprising the step of:  
10 heating the preform by internal friction during the twisting step.

81. The method of claim 57 further comprising the step of: heating the preform in a bath of heated liquid.

82. The method of claim 80 wherein the liquid is comprised of a salt solution.

15 83. The method of claim 80 wherein the liquid is comprised of oil.

84. The method of claim 57 wherein the twisting step includes the steps of:

securing the first end of the file preform in a rotatable collet;

securing the working length of the preform at a position

5 proximate to the collet in a slidable non-rotatable work holder at a predetermined distance from said collet;

rotating the collet and the portion of the file preform proximate the collet; and

increasing the distance between said collet and said work

10 holder.

85. The method of claim 83 wherein,  
the rotating step is performed at a predetermined rotation rate;  
the distance increasing step is performed at a predetermined axial speed; and further comprising the step of:

15 controlling the rotation rate and the speed to form a file having a predetermined twist rate.

86. A superelastic endodontic file comprising:

a shaft formed from a superelastic rod having a working length;

20 at least three cutting apices with adjacent cutting apices defining surfaces therebetween, said apices being permanently helically

deformed along the working length of said shaft to form helically shaped cutting edges;

wherein the surfaces of the shaft between adjacent longitudinal cutting edges define elongated helical surfaces which are flat  
5 when viewed in transverse cross section.

87. A superelastic endodontic file comprising:

a shaft formed from a superelastic rod having proximal and distal ends with a working length therebetween, said proximal end including a handle section and said distal end including a tip;

10 four or more cutting apices helically arranged about said shaft along the working length;

wherein the working length of said shaft includes a transverse cross-sectional area which is substantially rhomboidal in shape.

88. The endodontic file of claim 86 wherein the working length is  
15 tapered such that the rhomboidal shape decreases in area toward the tip.

89. An endodontic file having a predetermined transverse cross-sectional shape including corners, the file comprising:

integral working length and handle sections formed of a  
20 material exhibiting superelasticity above an austenitic finish temperature  $A_f$  of the material with said working length having the predetermined transverse cross-sectional shape,

said working length being twisted about its longitudinal axis to permanently form helical cutting edges at the corners thereof.

90. The endodontic file of claim 89 wherein said material is selected from the group consisting of near-equiatomic Ni-Ti, Ni-Ti-Nb alloys,  
5 Ni-Ti-Fe alloys, Ni-Ti-Cu alloys, Ni-Ti-Nb alloys, beta-phase titanium and combinations thereof.

91. The endodontic file of claim 89 wherein said material is at least about 40 atomic percent Ti.

92. The endodontic file of claim 89 wherein said material is about  
10 50.8 atomic percent Ti and about 49.2 atomic percent Ni.

93. The endodontic file of claim 89 wherein said predetermined transverse cross-sectional shape is selected from the group consisting of three and four sided polygons.

94. The endodontic file of claim 89 wherein said predetermined  
15 transverse cross-sectional shape is substantially rhomboidal.

95. The endodontic file of claim 94 wherein said rhomboidal shape has angles of about 60°-120°-60°-120°.

96. An endodontic file comprising:

a shaft including a working length portion formed of a material exhibiting superelastic characteristics, said working length portion having a predetermined transverse cross sectional area, a longitudinal axis, and a plurality of apices defining cutting edges,

said working length portion being permanently plastically deformed by twisting about its longitudinal axis to form said cutting edges at the apices thereof.

97. The endodontic file of claim 96 wherein said working length includes at least three of said cutting edges helically arranged about the working length of said shaft.

98. The endodontic file of claim 96 further comprising:  
helical surfaces arranged between adjacent cutting edges, said helical surfaces being substantially flat when viewed in transverse cross section.

99. The endodontic file of claim 96 wherein said working length includes at least four of said cutting edges helically arranged along said shaft.

100. The endodontic file of claim 99 further comprising:  
a flat side arranged between adjacent cutting edges.

101. The endodontic file of claim 96 wherein said metal is selected from the group consisting of near-equiatomic Ni-Ti, Ni-Ti-Nb alloys, Ni-Ti-Fe alloys, Ni-Ti-Cu alloys, Ni-Ti-Nb alloys and beta-phase titanium.

102. The endodontic file of claim 96 wherein said metal is at least  
5 about 40 atomic percent Ti.

103. The endodontic file of claim 96 wherein said material is about 50.8 atomic percent Ti and about 49.2 atomic percent Ni.

104. The endodontic file of claim 96 wherein said predetermined transverse cross-sectional shape is selected from the group consisting of  
10 three and four sided polygons.

105. The endodontic file of claim 96 wherein said predetermined transverse cross-sectional area has a substantially rhomboidal shape.

106. The superelastic file of claim 105 wherein said substantially rhomboidal shape has angles of about 60°-120°-60°-120°.

107. Apparatus for forming an endodontic instrument from a superelastic rod-shaped blank, the apparatus comprising:

a linear motion mechanism including a clamping element for holding a portion of said blank and moving said clamping element along said  
5 blank;

a rotary motion mechanism for holding and rotating said instrument, said rotary motion mechanism being operatively coupled to said linear motion mechanism for rotating said blank as said clamping element moves therealong to form a helically fluted instrument; and

10 a source of heat disposed proximate said linear and rotary motion mechanisms for heating said blank at least prior to operation of the linear and rotary motion mechanisms.

108. The apparatus of claim 107 wherein the source of heat is an electrical heating source selected from the group consisting of radiant,  
15 joulian and conductive types of heating sources.

109. The apparatus of claim 107 wherein the source of heat is a heated liquid.

110. The apparatus of claim 109 wherein said liquid is contained in a vessel operatively coupled to a heating element with said linear and rotary  
20 motion mechanisms mounted above said vessel for vertical movement into said vessel.

111. The apparatus of claim 110 wherein said liquid contains a salt.
112. The apparatus of claim 107 wherein said rotary motion mechanism includes a collet adapted to hold an endodontic file blank.

INTERNATIONAL APPLICATION PUBLISHED UNDER THE PATENT COOPERATION TREATY (PCT)

(51) International Patent Classification <sup>7</sup> : A61C 5/04		A3	(11) International Publication Number: WO 99/37235
			(43) International Publication Date: 29 July 1999 (29.07.99)
(21) International Application Number: PCT/US99/00895		(81) Designated States: AL, AM, AT, AU, AZ, BA, BB, BG, BR, BY, CA, CH, CN, CU, CZ, DE, DK, EE, ES, FI, GB, GD, GE, GH, GM, HR, HU, ID, IL, IN, IS, JP, KE, KG, KP, KR, KZ, LC, LK, LR, LS, LT, LU, LV, MD, MG, MK, MN, MW, MX, NO, NZ, PL, PT, RO, RU, SD, SE, SG, SI, SK, SL, TJ, TM, TR, TT, UA, UG, UZ, VN, YU, ZW, ARIPO patent (GH, GM, KE, LS, MW, SD, SZ, UG, ZW), Eurasian patent (AM, AZ, BY, KG, KZ, MD, RU, TJ, TM), European patent (AT, BE, CH, CY, DE, DK, ES, FI, FR, GB, GR, IE, IT, LU, MC, NL, PT, SE), OAPI patent (BF, BJ, CF, CG, CI, CM, GA, GN, GW, ML, MR, NE, SN, TD, TG).	
(22) International Filing Date: 15 January 1999 (15.01.99)			
(30) Priority Data: 09/014,139                      27 January 1998 (27.01.98)                      US			
(71) Applicant: KERR CORPORATION [US/US]; 1717 West Collins Avenue, Orange, CA 92867 (US).			
(72) Inventors: FARZIN-NIA, Farrokh; 141 West Fairview Boulevard, Inglewood, CA 90302 (US). OTSEN, William; 846 E. Huerta Verde Road, Glendora, CA 91741 (US). GARMAN, Gary; 2541 2nd Street, La Verne, CA 91750 (US).		Published With international search report.	
(74) Agents: ROONEY, Kevin, G. et al.; Wood, Herron & Evans, L.L.P., 2700 Carew Tower, Cincinnati, OH 45202 (US).		(88) Date of publication of the international search report: 22 June 2000 (22.06.00)	

(54) Title: SUPERELASTIC ENDODONTIC INSTRUMENT, METHOD OF MANUFACTURE, AND APPARATUS THEREFOR

**(57) Abstract**

A superelastic endodontic instrument, such as a file (11), is formed by grinding a superelastic wire (8) to form a file preform or blank (12), and rotating a first end of the blank (12) while preventing rotation of a second end of the blank (12). The file blank (12) is maintained in the austenite phase at least until twisted to form a stress induced martensite which is plastically deformed by the twisting. A heat treatment step may be performed prior to twisting, during twisting or after twisting of the preform or blank (12). The file blank (12) may be heated by electrical heating methods or by submerging the blank in a heated liquid (234).

# INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US99/00895

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) :A61C 5/04  
US CL :433/102; 451/48

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 433/102; 451/48

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched  
NONE

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)  
NONE

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A,P	US 5,775,902 A (MATSUTANI et al.) 07 July 1998, entire document.	1-112
A	US 5,628,674 A (HEATH et al.) 13 May 1997, entire document.	1-112
A	US 5,464,362 A (HEATH et al.) 07 November 1995, entire document.	1-112

☐ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier document published on or after the international filing date	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&" document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means	
"P" document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search

02 MARCH 2000

Date of mailing of the international search report

05 APR 2000

Name and mailing address of the ISA/US  
Commissioner of Patents and Trademarks
